1982 — 1998**

**DIGEST
OF
PRODUCTIVITY
AND
COMPETITIVENESS STATISTICS
1982 — 1998**

Foreword

In December 1998, this office published a report entitled "Productivity and Competitiveness Indicators, 1982 - 1997". This topic will henceforth be the subject of a separate digest, which is expected to be published every year. The present publication is the first issue of this digest and carries Vol.2 to be in line with the first report, which carried Vol.1.

Data presented in this digest pertain to the period 1982 to 1998 and they refer to the whole economy, and in particular to the manufacturing sector. Within manufacturing, data are presented separately for the Export Processing Zone (EPZ), which is itself subdivided into Textile and Non textile subsectors. All estimates have been worked out from data available as at September 1999 and are different from those released in Issue No 304 of the "Economic and Social Indicators", which were based on data available in March 1999.

It is hoped that these statistics will assist decision makers, planners, the business community and the public in general to monitor and analyse the implications of productivity and competitiveness at the national and sectoral levels.

For the preparation of this report, information was obtained from various institutions, local and international. The collaboration of these institutions is gratefully acknowledged.

Executive Summary

Productivity measurement at national level

There are many definitions of productivity and quality. This is partly due to their complex nature and partly because they mean different things to different people. The main idea, however, is the relation between output and inputs in a production process.

At national level, output is measured by value added (at constant prices) which is the additional value created in the production process. Value added is thus an unduplicated measure of output, in which the value of goods and services used as intermediate inputs are discounted from the value of the output.

Productive wealth in an economy is generally achieved through the use of two main inputs namely labour and capital. Labour input is given by the total number of persons engaged whereas capital is given by the stock of fixed capital.

If output grows faster than inputs, then productivity is improving, and an increase in real income should eventually follow. In this way, productivity improvement boosts economic growth and hence the economy produces more and more.

Table I. Productivity and other related indicators, total economy.

Indicator	Average growth rate (%)	
	1982 - 1998	1990 - 1998
1. Output (GDP)	5.7	5.5
2. GDP per capita	4.7	4.3
3. Capital stock	6.3	6.5
4. Capital productivity	-0.6	-1.0
5. Labour input (Employment)	3.4	1.9
6. Labour productivity	2.2	3.5
7. Multifactor productivity	0.5	0.8
8. Unit labour cost (Mauritian Rupees)	7.6	6.4
9. Unit labour cost (U.S.Dollars)	2.5	0.3

Gross domestic product (GDP)

Between 1982 and 1998, GDP in real terms, grew on average by 5.7 per cent per year. After a modest growth of only 0.4 per cent in 1983, growth accelerated to 7.8 per cent for the period 1985 to 1988, thereafter maintaining an average annual growth of 5.6 per cent.

Labour and capital inputs

During the period under study, 1982 to 1998, labour input increased by 3.4 per cent per annum. After increasing by around 6 per cent in the first five years, employment growth slowed down to 2.1 per cent in the last ten years. On the other hand, capital input as measured by the stock of fixed capital, grew at an average rate of around 6.3 per cent over the whole period.

Labour productivity

Labour productivity, the outcome of the interaction between output and labour input grew by an average of 2.2 per cent over the period 1982 to 1998. After an initial period of low productivity growth (with the index exceeding 100 only in 1988) labour productivity picked up and grew by 3.5 per cent annually during the last eight years.

Capital productivity

Capital productivity declined by 0.6 per cent over the sixteen year period, 1982 to 1998. During the initial five years period, a growth rate of 1.8 per cent was achieved, implying better utilisation of productive equipment and a simultaneous vigorous increase in employment. This initial rise was, however, followed by continuous decline and eventual stabilisation.

Multifactor productivity

The ratio of the combined effects of labour and capital is reflected in the multifactor productivity (MFP). Multifactor productivity grew at an annual rate 0.5 per cent, during the period 1982 to 1998. A relatively higher growth of 0.8 per cent was recorded during the period 1990 and 1998, reflecting a better balance between output and labour and capital inputs.

Unit labour cost

Unit labour cost (ULC) is the labour cost per unit of real output. It shows how well increases in wage per worker are offset by improved productivity performance and as such gives an indication of competitiveness.

Between 1982 and 1998, ULC in Mauritian rupees grew on average by 7.6 per cent but in U.S Dollar terms, the growth works out to 2.5 %.

Structure of the economy: 1982 and 1998

A comparison of value added by industry group in 1982 and 1998 shows a gradual shift in the contribution of the different sectors to GDP. The share of Agriculture decreased from 15.3 per cent in 1982 to 8.7 per cent in 1998 whilst that of Manufacturing increased to from 15.6 per cent in 1982 to 24.9 percent in 1998.

Table II. Contribution of each sector to the economy : 1982 and 1998

Industry group	Rupees million			
	1982		1998	
	Value added	%	Value added	%
Agriculture and fishing	1530	15.3	7296	8.7
Mining and quarrying	17	0.2	127	0.2
Manufacturing	1560	15.6	20932	24.9
<i>EPZ</i>	449	4.5	10393	12.4
Electricity, gas and water	260	2.6	1433	1.7
Construction	625	6.2	5030	6.0

All sectors	10020	100.0	84100	100.0

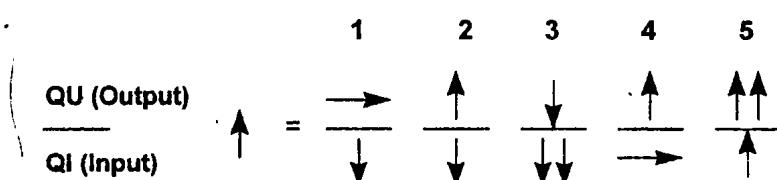

CHAPTER 1

APPROACH TO PRODUCTIVITY MEASUREMENT

1.1 The relevance of productivity measurement

Productivity measurement makes use of ratios calculated by comparing output to one input or a combination of inputs in a particular industry, sector or for the entire economy. The ratio of output to labour or capital gives partial productivity indicators, and the ratio of output to all inputs is termed total factor productivity (TFP). However, as data is not available to estimate all inputs, a less specific term, multifactor productivity (MFP) is used.

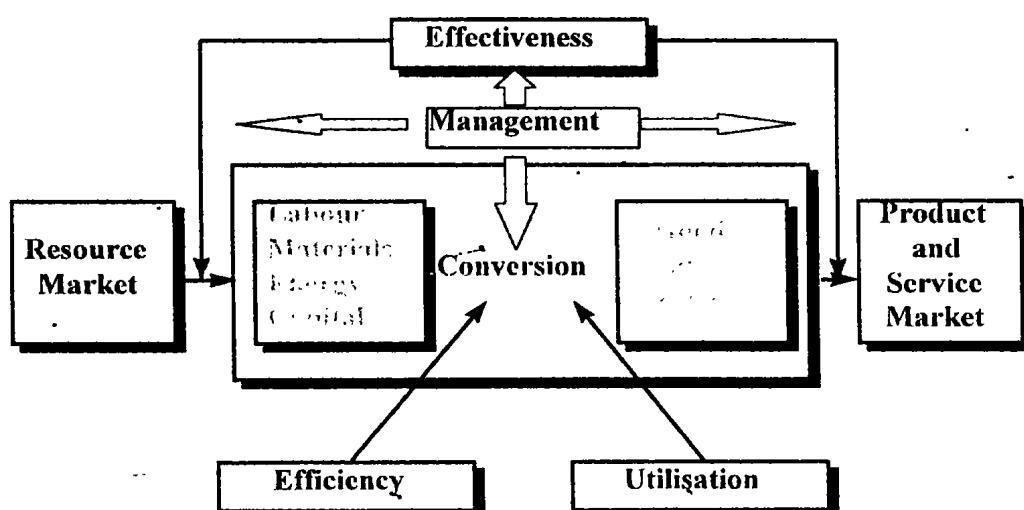

The productivity ratio can increase in five ways:

For countries with growing workforces or high unemployment rates options 4 and 5 are usually preferred as it does not involve reductions in input and therefore does not pose a threat to employment. Most cost reduction exercises usually entail the retrenchment of labour, as it is a mobile and therefore vulnerable resource.

1.2 The Productivity process

Fig1.1 The Productivity Process

Productivity improvement is brought about in many ways. For instance, producing the "right products and services" (*effectiveness*) will lead to an increase in demand, which usually means better utilisation of capacity. Productivity may also be enhanced through more competent management or better allocation of existing resources, resulting in a higher rate of conversion (*efficiency*) or greater use (*utilisation*) of these resources.

1.3 Coverage

Until recently only labour productivity and unit labour cost indices were being computed by this office. Indices for the overall Manufacturing and Export Processing Zone sectors and covering **only large enterprises**, that is, those employing ten or more workers, were available.

An estimate of capital stock has enabled the computation of partial capital productivity and multifactor productivity (MFP) indices. The new series apply to all production units including small units working with nine or fewer workers.

1.4 Status of figures

Data series presented in this report are the latest available as at end of September 1999. Some are provisional and are therefore subject to revision in later issues. The series in this issue supersede those appearing in the previous one. The status of the figures presented is as follows:

1997	Revised estimates
1998	First estimates

1.5 Caution to users

Productivity measures are usually expressed as fractions transformed into index numbers making use of a reference base period. Index numbers provide reliable and timely estimates of productivity change and focus is on trends as opposed to levels.

Since productivity statistics are derived from ratios, they should be used and interpreted with caution. A rise in output per unit of a single input will measure the combined effect of a change in the efficiency with which all resources have been used. For example, output per worker will rise if labour is equipped with better tools and machinery. A better measure of productivity, using multiple resources, is given by the Multifactor productivity.

While comparing productivity indicators, it is important to pay attention to their coverage. For the purpose of productivity analysis, some countries refer to the private business sector only

Data series on productivity and competitiveness indicators presented in this report relate to all production units in the:

- (a) Total economy
- (b) Manufacturing sector and
- (c) Export Processing Zone (EPZ) and its two subsectors, textile and non textile.

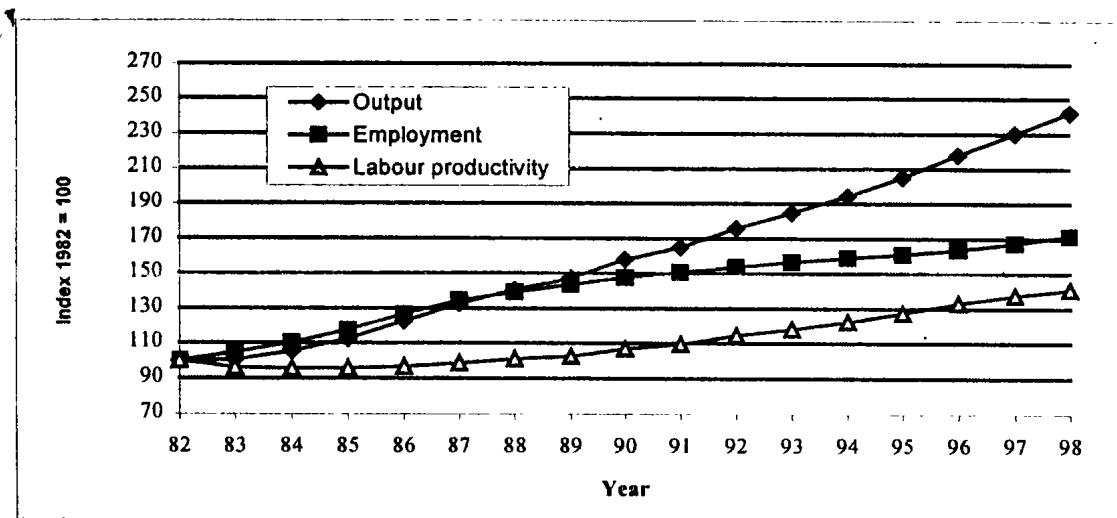

CHAPTER II

PRODUCTIVITY OF THE TOTAL ECONOMY

2.1 Trends in labour productivity

Labour productivity for the total economy is calculated by dividing Gross Domestic Product (GDP) by the number of people employed. An increase in GDP per worker could mean that GDP increased at a higher rate than employment, while a decline could indicate that the same GDP was produced by more employees.

Figure 2.1 - Labour Productivity and its components, 1982 to 1998

Note: For Mauritius it is the total economy whereas in other countries they usually exclude the public sector (general government) and its enterprises and show the figure for only the private business sectors.

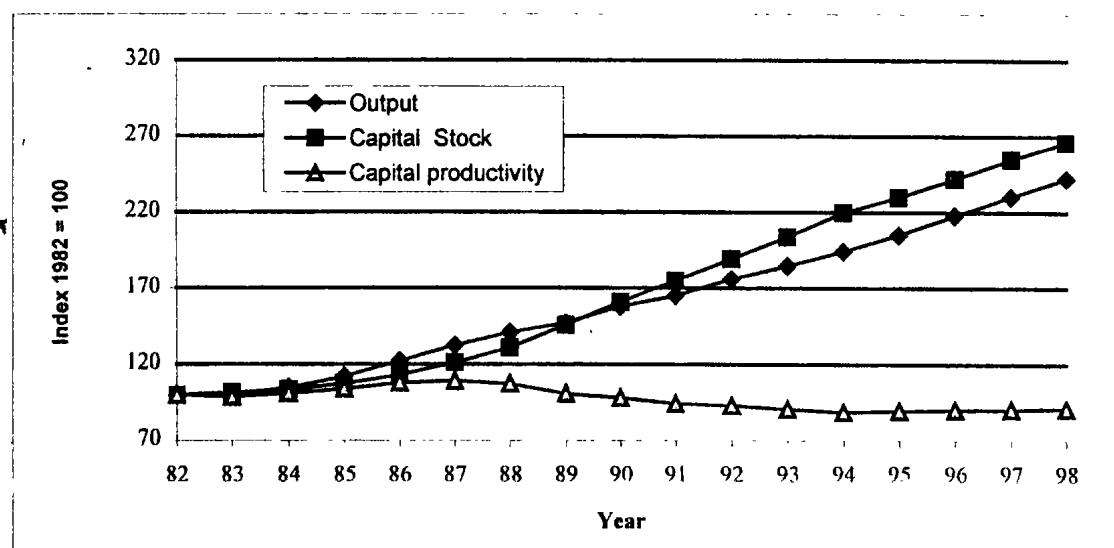

The period 1982 to 1985 showed negative growth in labour productivity, which on average declined by 1.4 per cent. This was the result of an increase in employment which exceeded the increase in GDP. From 1985 onwards, the index showed positive growth since increases in GDP exceeded employment growth. GDP per worker growth averaged 1.8 per cent per annum from 1985 to 1988, 3.2 per cent from 1989 to 1992 and 3.8 per cent from 1993 to 1998. The average growth over the whole period 1982 to 1998 was 2.2 per cent per annum.

Some of the changes in GDP growth or employment growth could have resulted from other factors, such as improved government incentives, better international marketing, more intensive training or the utilisation of more sophisticated machines and technology. Labour productivity as measured by GDP per worker is therefore not a very precise measure of productivity, but nevertheless gives an indication of fluctuations in the labour productivity trend. As the figures to calculate it are usually readily available, it is widely used internationally as a measure of productivity.

2.2 Trends in capital productivity

Capital productivity is defined as the ratio of real output to the stock of fixed capital used in the production process. For the economy as a whole, it is measured by dividing Gross Domestic Product (in constant prices) in a given year by the fixed capital stock (at constant prices) used to produce it. Capital productivity gives an indication of how efficiently capital assets are being used.

Figure 2.2 - Capital Productivity and its components , 1982 to 1998

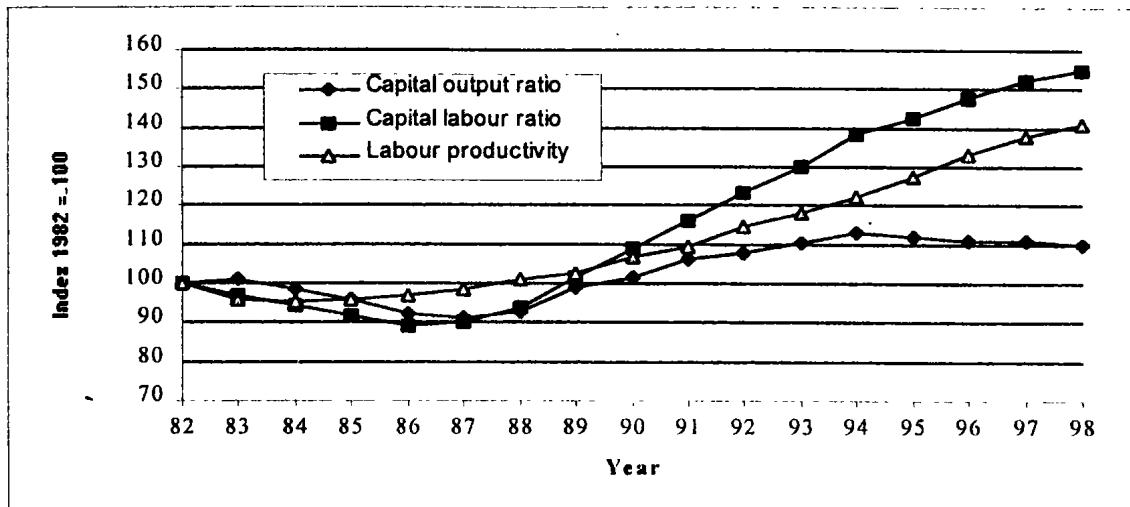

The trend in capital productivity can be classified into three distinct phases: 1982 – 1987, 1988 – 1994 and 1995 – 1998. From 1982 to 1987, a capital productivity growth rate of 1.8 per cent was realised implying better utilisation of productive equipment coupled with a vigorous increase in employment. The second phase 1988 to 1994, registered a decline in capital productivity with an average drop of 3.2 per cent per annum. During this phase, growth in output (5.5 per cent) was exceeded by growth in capital input (9 per cent) which resulted in the drop in capital productivity. The last three years suggest a consolidation phase with a slight 1.1 per cent growth in 1995 and 1996 followed by an average increase of 0.4 per cent in 1998 and 1999. These four years saw a stagnation in the rate of increase in capital input, which resulted in the improvement in capital productivity. Over the entire period, capital productivity declined by 0.6 per cent per annum.

2.3 Capital labour ratio and capital output ratio

Capital labour ratio is the amount of capital used per worker and gives an indication of the capital intensity of the process. Capital output analysis shows the capital needed to produce one unit of output, both measured in real terms.

Figure 2.3 - Capital Labour Ratio , 1982 to 1998

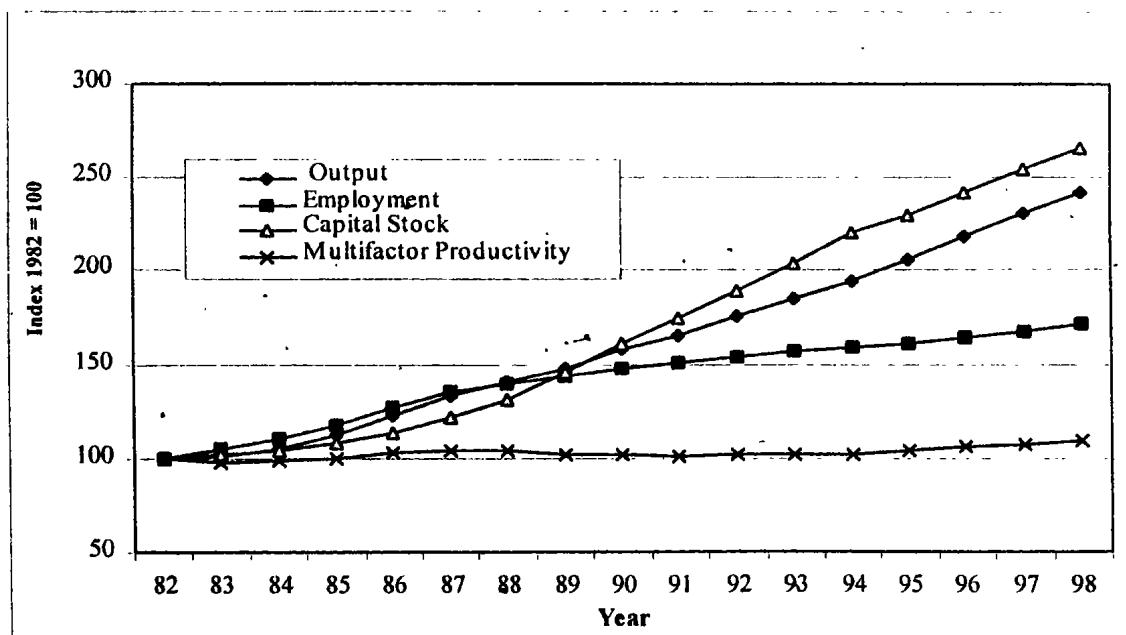

From fig 2.3 a slight decline in the capital labour ratio is observed from 1982 to 1987 implying the use of more capital per worker as a result of investment in better technology. However an increase of 5.1 per cent per annum is noted from 1988 to 1998, in the capital/labour ratio which enabled workers to be more productive.

2.4 Trends in multifactor productivity

Multifactor productivity measures output against both capital and labour employed. It gives an indication of the contribution to output per unit of combined capital and labour inputs, and of factors other than labour or capital. These factors could include better quality products and services, economies of scale, improved access to foreign markets, better management and improved training.

Figure 2.4 - Multifactor productivity and its components, 1982 to 1998

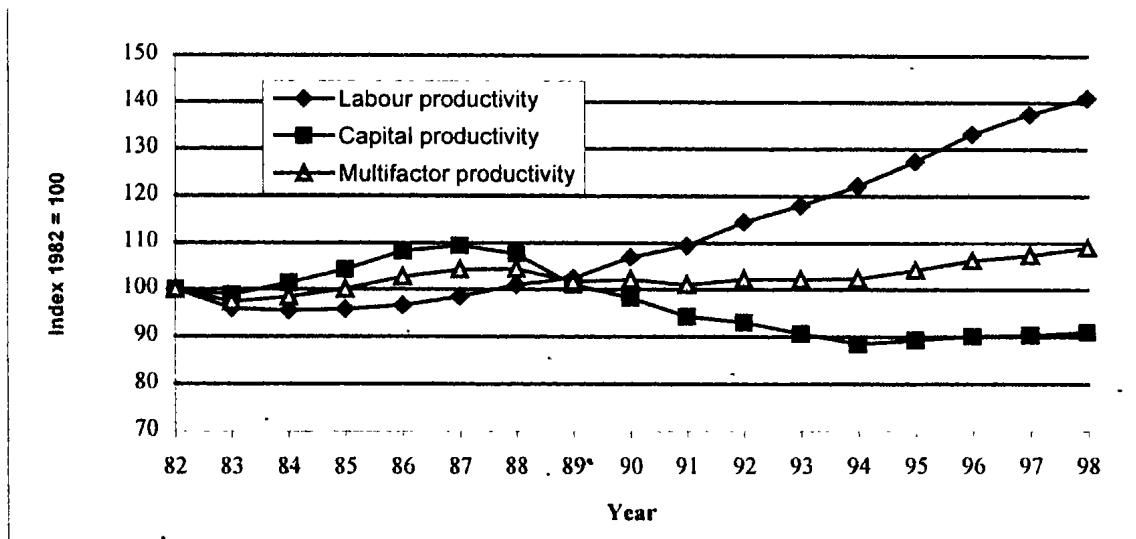

In 1983, the increase in output was less than the increase in both labour and capital inputs. The effect of this was a drop of 2.6 per cent in multifactor productivity. Between 1984 and 1987, increases in output accelerated to eclipse the large increases in both capital and labour, resulting in a multifactor productivity growth of 1.9 per cent over this period. From 1988 to 1991, a small decline of 1 per cent was recorded in the multifactor productivity due to a large increase in capital input and a relatively smaller increase in output and labour input. However, it was not enough to offset the growth in use of capital. Between 1994 and 1998, a small multifactor productivity growth rate of 1.6 per cent was recorded reflecting a better balance between output, labour and capital inputs. Over the entire period from 1982 to 1998, multifactor productivity increased by 0.5 per cent per annum.

2.5 Comparison of productivity trends

Multifactor productivity is important because it focuses attention on both human capital and equipment. This means that a well educated and highly trained labour force is capable of increasing productivity, and hence living standards.

For many countries especially islands and city economies like Mauritius and Singapore which have limited resources, productivity growth becomes imperative and crucial. In Mauritius, it is evident that economic growth was initially driven by employment creation. In the longer term, it is envisaged that the massive injections in capital equipment and new technology, especially in telecommunications and transport, will provide the opportunity for future improvements in multifactor productivity.

Figure 2.5 – Capital, labour and multifactor productivity , 1982 to 1998

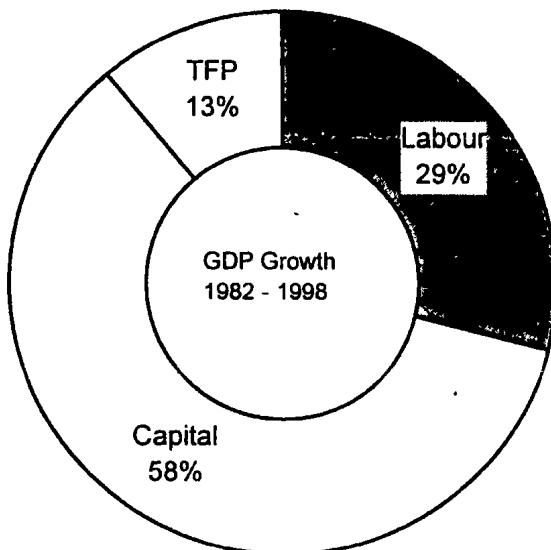

As far as capital productivity is concerned, there is a distinct turning point in 1987. The first phase, from 1982 to 1987, shows sustained growth. Thereafter, capital productivity declined by an average of 1.7 per cent per annum. Labour productivity, on the other hand, has increased steadily from 1984 onwards. Multifactor productivity, which reflects the combined effects of labour and

capital, grew until 1988, reflected a mixed performance between 1989 and 1994, and has grown by 1.5 per cent per annum during 1995 and 1998.

2.6 Growth accounting

Growth accounting is a subject area which enables an analysis of the contribution of different factors to economic growth.

**Fig 2.6 - Contribution of labour, capital and total factor productivity to growth
1982 – 1998**

Between 1982 and 1998, Gross Domestic Product in real terms grew by 5.7 per cent. The contribution of labour, capital and other factors to the 5.7 growth was as follows:

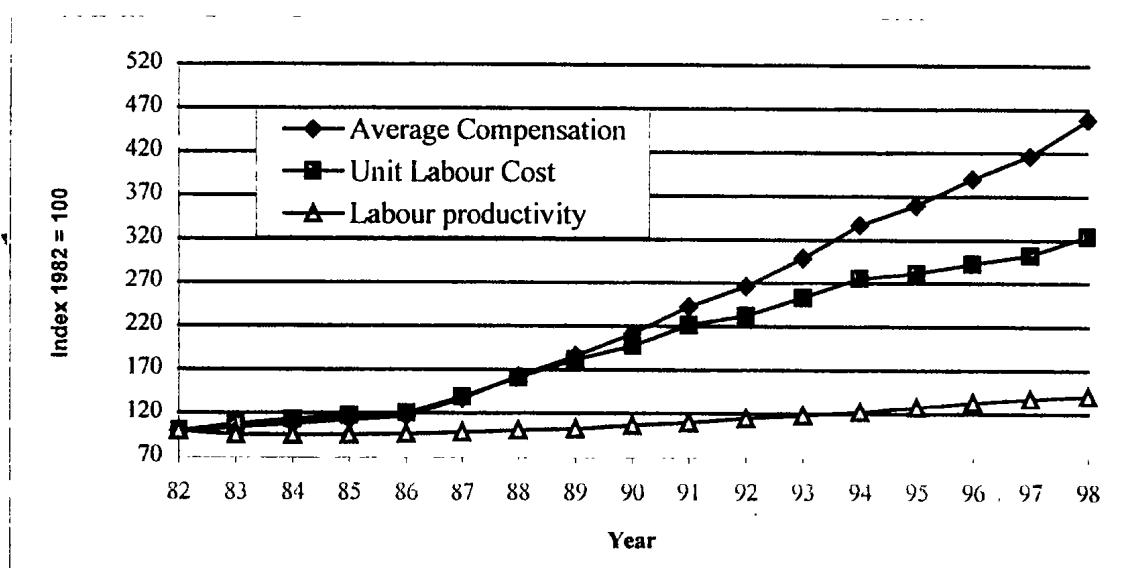

Factors	Percentage
Labour	29 %
Capital	58 %
“Other factors” (TFP)	13 %

The “other factors” are sometimes also referred to as the residual or total factor productivity (TFP). During the same period labour grew by 3.4 per cent and capital by 6.3 per cent. Growth in TFP is that part of change in output that has not been explained by corresponding changes in labour and capital inputs. It includes qualitative factors such as training, management and technology.

2.7 Unit labour cost - The effects of labour cost

Unit labour cost is the remuneration of labour for producing one unit of output. Remuneration of labour includes wages and salaries, plus all contributions made by employers for their employees. Unit labour cost can also be measured as the ratio of labour cost (average compensation) per worker and labour productivity. This definition emphasises the competitiveness angle of unit labour cost.

Figure 2.7 - Unit Labour Cost, 1982 to 1998

Between 1982 to 1986, labour cost per worker increased on average by 4.9 per cent, accelerated sharply to 12.9 per cent from 1987 to 1991 and levelled off to 5.7 per cent between 1992 and 1998. Unit labour cost increased by 7.6 per cent per annum during the period under review. This increase was partly offset by the average growth in labour productivity of 2.2 per cent per annum. The rise of 7.6 per cent in the unit labour cost must be viewed against an average inflation rate of 7.0 per cent per annum. Unit labour cost is an important indicator of international competitiveness and it is also discussed in chapter IV on International Competitiveness.

CHAPTER III

PRODUCTIVITY OF MANUFACTURING AND THE EXPORT PROCESSING ZONE (EPZ)

Background

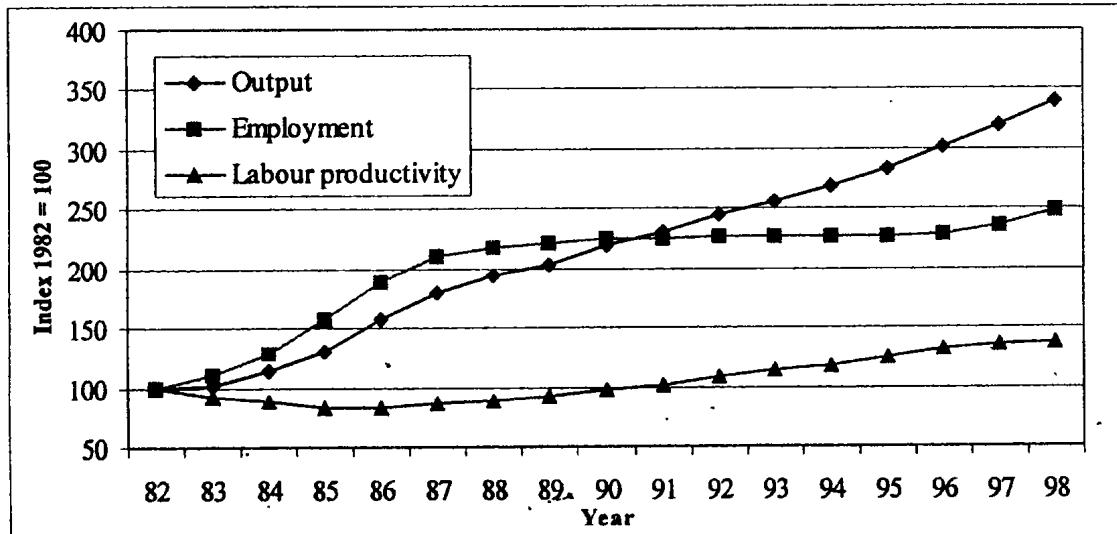

Since the early 1980's, the manufacturing sector has made giant strides, raising its contribution to GDP from 15 per cent in 1982 to around 25 per cent in 1998. In 1998 employment in the manufacturing sector accounted for nearly 30 per cent of total employment and for some 60 per cent of aggregate foreign earnings. The lifeblood of the Manufacturing sector has been the EPZ companies which accounted for some 50 per cent of Manufacturing's value added in 1998.

The productivity performance of the manufacturing sector can be divided into two distinct phases: 1982 to 1988 and 1989 to 1998. From 1982 to 1988, the manufacturing sector was characterised by high growth of both labour and capital input mainly due to the EPZ sector. However, the period 1989 to 1998 witnessed a stabilisation in labour and a slight increase in capital input. Both labour and capital productivity therefore showed positive growth and yielded a higher rate of multifactor productivity.

3.1 Labour productivity

The outcome of the interaction between output and labour input is reflected in the labour productivity index.

Figure 3.1 - Labour Productivity in Manufacturing, 1982 to 1998

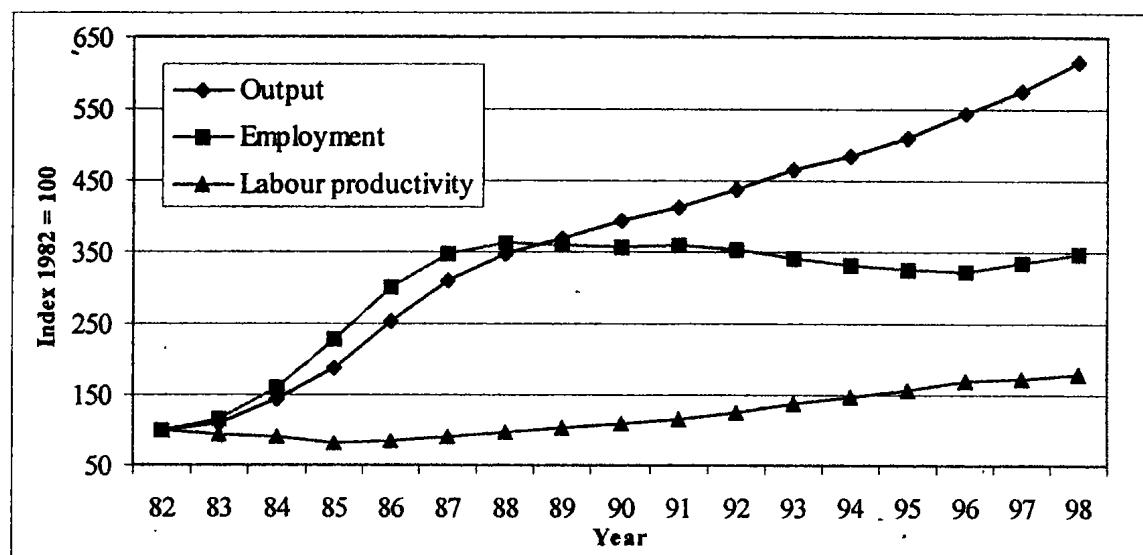

During the period 1982 to 1985, labour productivity in the overall manufacturing sector declined at an annual rate of 6.2 per cent, as the 16.5 per cent growth rate in labour input outstripped the growth rate of real output (9.3 per cent). High labour mobility and absenteeism coupled with low level of efficiency due to the learning gap were major factors contributing to the decline in labour productivity. Developments in the manufacturing sector have been substantially influenced by growth experienced by EPZ enterprises.

As shown in fig.3.2, labour productivity in the EPZ sector reflected a declining trend between 1982 and 1985 (6.2% annually) and grew by 6.5 per cent between 1986 and 1989 and 6.2 per cent from 1990 onwards.

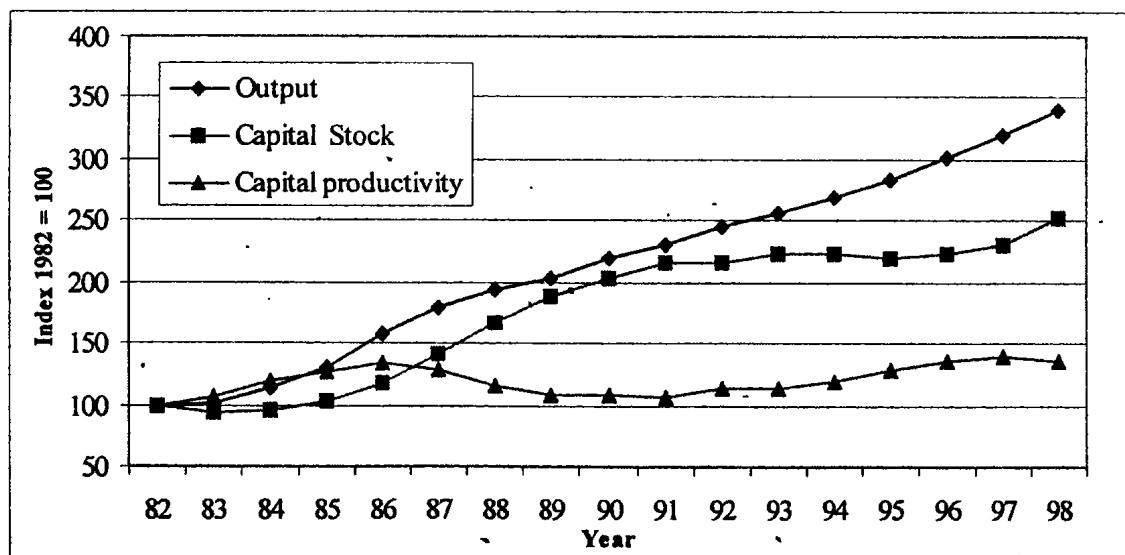

This healthy situation may be attributed to the production of higher value added products, longer working hours due to more shift work and increasing use of capital intensive technologies in the textile and clothing sector.

Figure 3.2 - Labour Productivity of the Export Processing Zone, 1982 to 1998

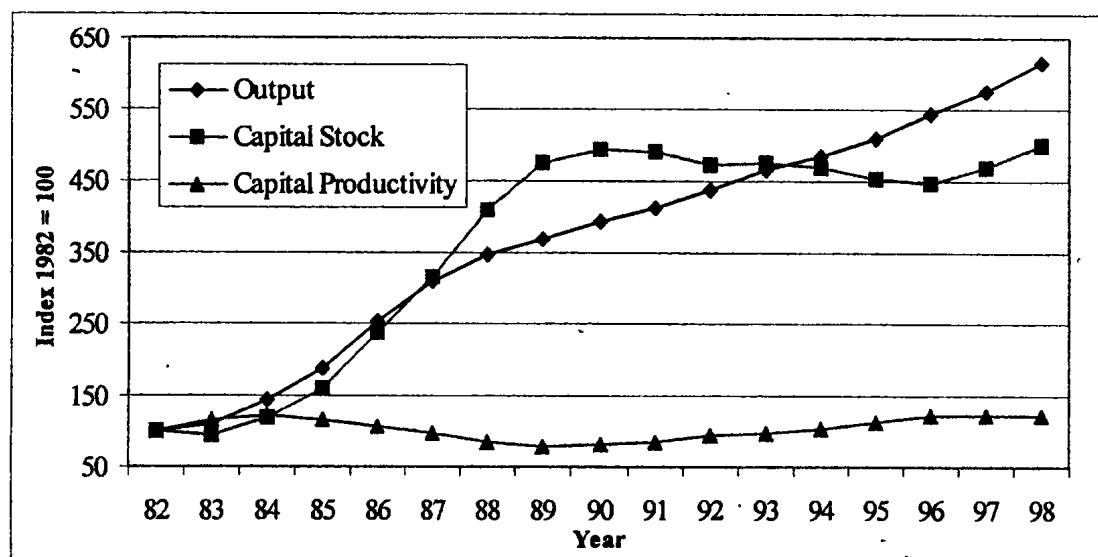

3.2 Capital productivity

Figure 3.3 - Capital Productivity in Manufacturing, 1982 - 1998

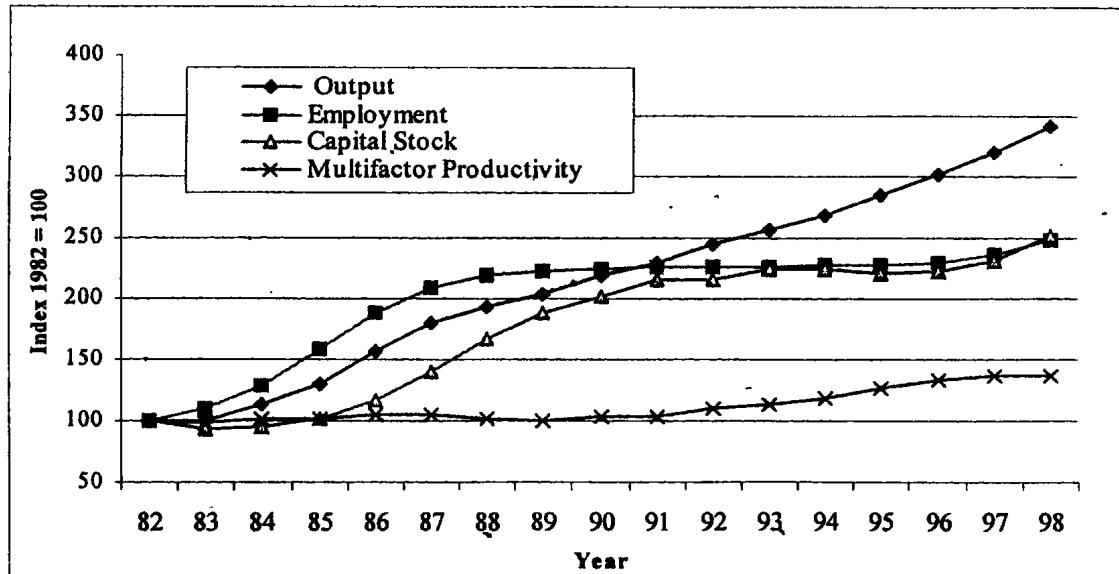

As shown in figure 3.3, the trend in capital productivity over the period under review, was somewhat erratic. After increasing by an annual average rate of 7.5 per cent during 1982 to 1986, due to better utilisation of equipment, capital productivity decreased by 6.9 per cent per annum from 1987 to 1989. This decrease is a consequence of substantial investment, which rose by 17.2 per cent per annum between 1987 and 1989. Capital productivity revived from 1992 onwards, reflecting greater efficiency in the use of capacity. Developments in the manufacturing sector were substantially influenced by growth in the EPZ sector.

Figure 3.4 - Capital Productivity of the Export Processing Zone, 1982 - 1998

3.3 Multifactor productivity

Figure 3.5 - Multifactor Productivity in Manufacturing, 1982 - 1998

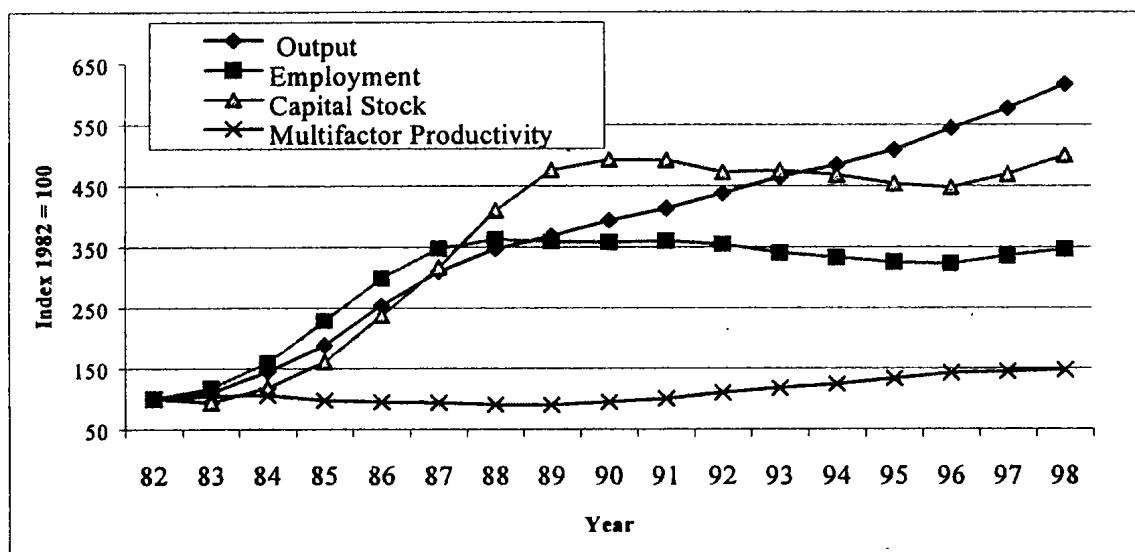

Since 1982, output has risen steadily while the increase in both employment and capital stock were high prior to 1989, thereafter tapering to current levels. It is clear from figure 3.5 that between 1982 and 1989, the rate of output increased at a higher rate than that of capital, and in this way the high growth in employment could be offset by improved efficiencies.

These gains in multifactor productivity denote maturity of the industrial structure and growth that is driven by factors such as efficiency, enhanced product quality and better management.

As regard the EPZ sector , Multifactor productivity shows a negative trend of 1.6 per cent up to 1989 and thereafter increased at an average rate of 5.7 per cent per annum.

Figure 3.6 - Multifactor Productivity of Export Processing Zone, 1982 - 1998

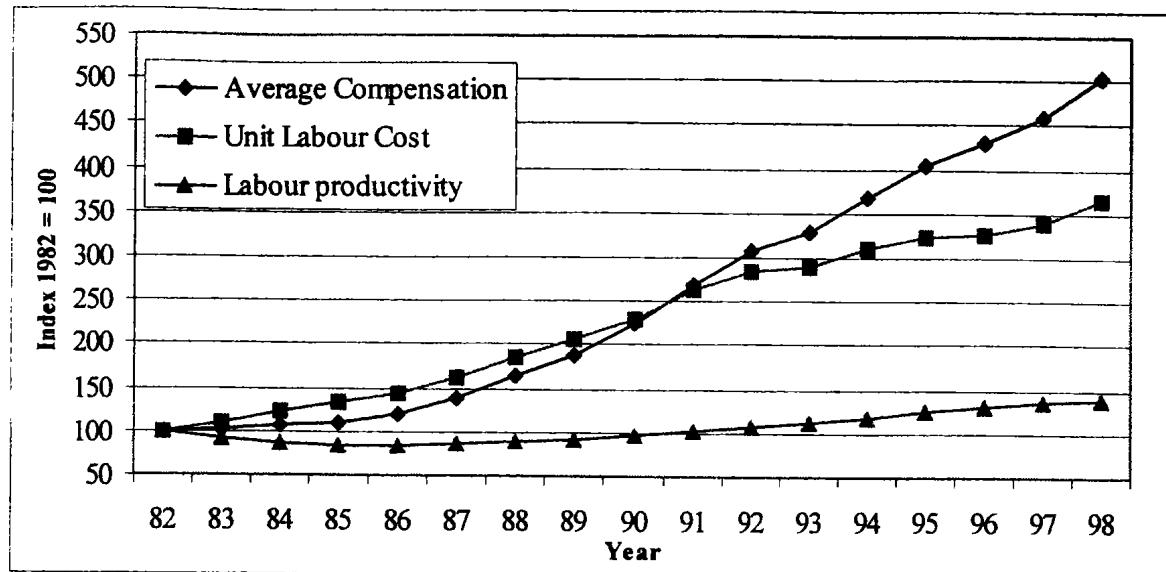

3.4 Unit labour cost

Many of the manufacturing enterprises, including the EPZ, started in Mauritius because of the relatively low labour cost and the abundance of labour. A major boost for growth in the manufacturing sector came from the introduction of the EPZ, which included generous incentives, such as duty free equipment and tax holidays.

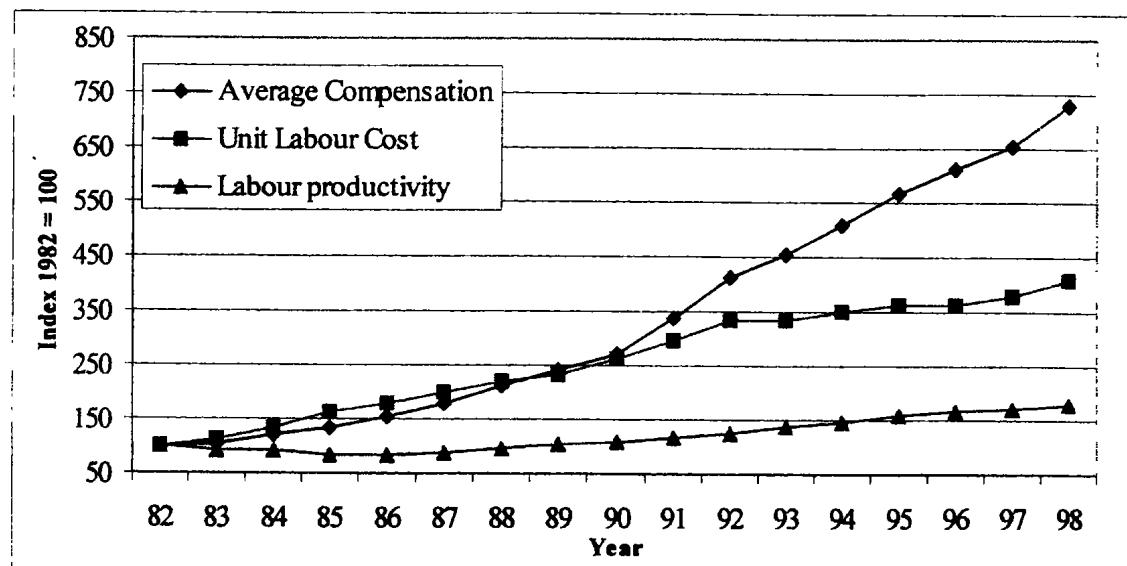

Between 1982 and 1985, unit labour cost increased more than average compensation due to a decline in labour productivity. Thereafter, labour productivity improved resulting in the unit labour cost increasing at a slower rate than the average compensation.

Figure 3.7 - Unit Labour Cost in Manufacturing, 1982 to 1998

Since 1992 compensation in the EPZ sector grew at an average rate of 10.1 per cent per annum and together with the continued labour productivity growth (6.3 per cent), unit labour cost was contained at 3.6 per cent. This trend resulted in an improvement in the competitiveness of the manufacturing sector.

Figure 3.8 - Unit Labour Cost of the Export Processing Zone, 1982 to 1998

Chapter IV

INTERNATIONAL COMPETITIVENESS

General

Competitiveness indicators can be used to make comparison of a country's competitiveness. Indicators used are unit labour cost, real effective exchange rate, net export ratios, relative market shares as well as qualitative indicators such as those mentioned in the World Competitiveness Year Book.

4.1 International comparison of Unit Labour Cost (ULC)

Labour is the most important resource in the production process as it is the only input that can transform other resources into products and services that have value. It is therefore appropriate to concentrate on the labour cost content of output to give an indication of the competitive ability of nations.

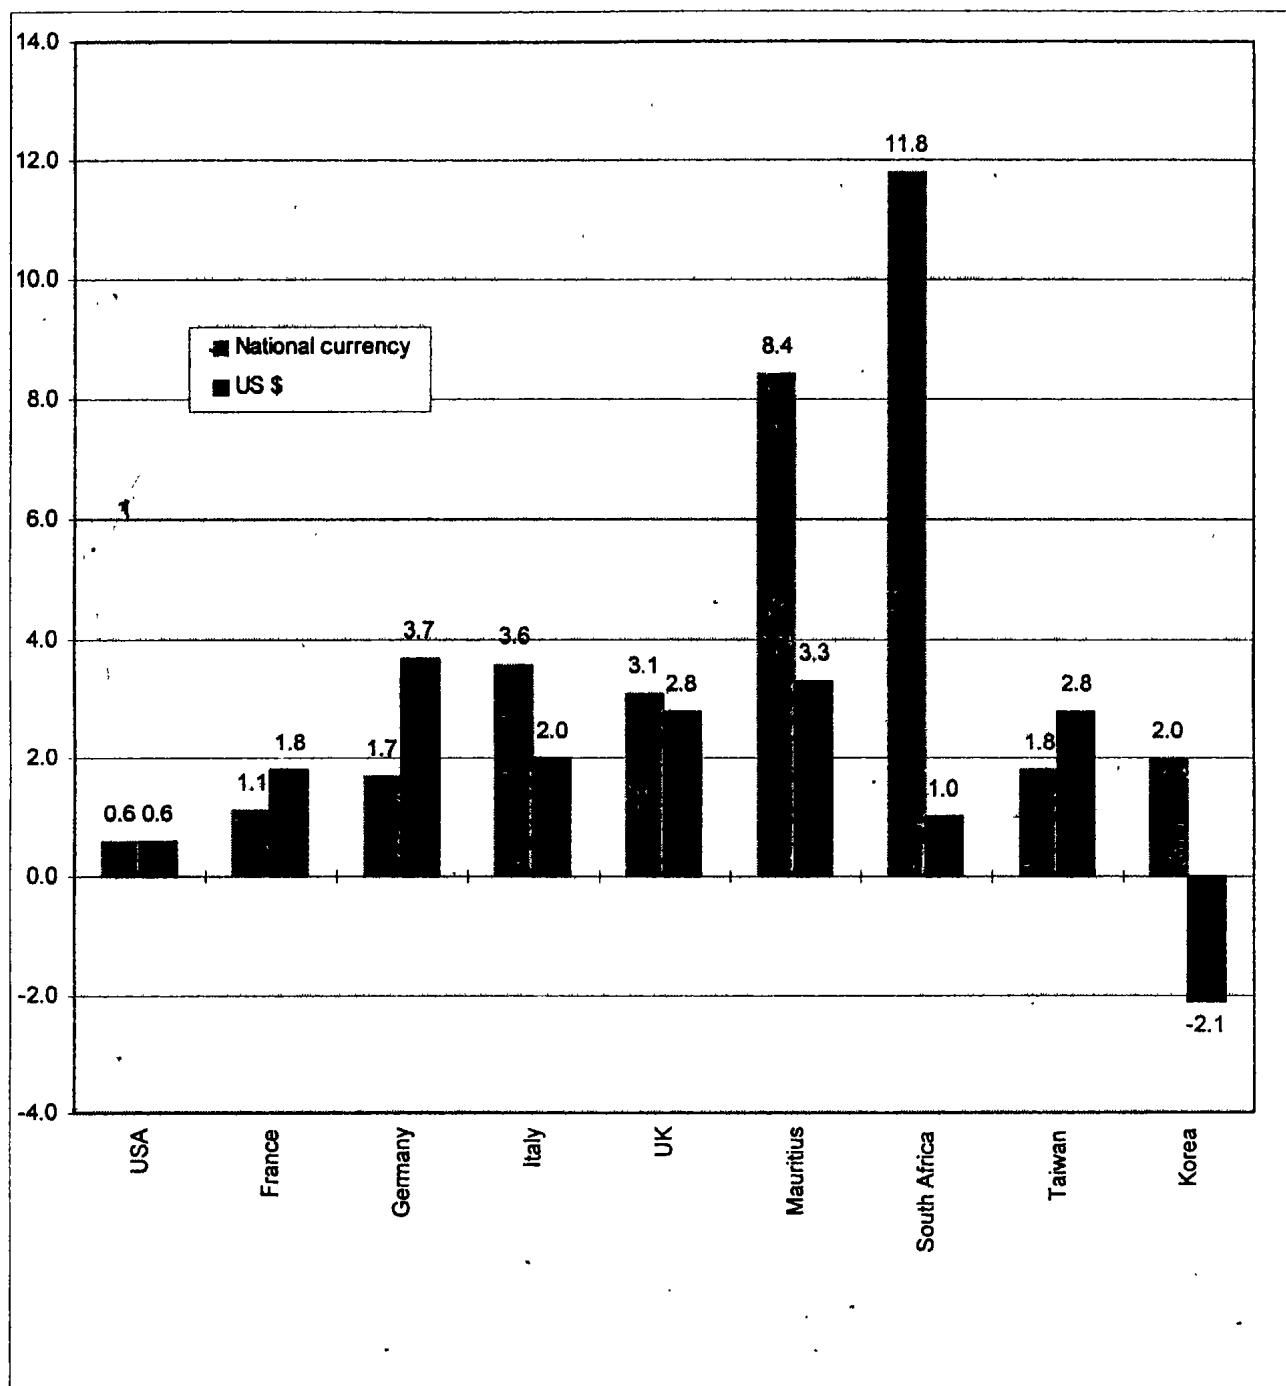

In examining trends in competitiveness, it is advisable to consider changes in foreign exchange rates, because competitiveness of products depends on changes in the prices of those products and changes in exchange rates. Unit labour cost is computed both in Mauritian rupee and U.S. Dollars. The dollar is chosen as the currency in which most international transactions are priced. The latter indicates comparative changes in unit labour cost after the movement in exchange rates have been considered.

4.2. International Comparison of Growth Rate in Unit Labour Cost in the Manufacturing sector, 1982 to 1998

Figure 4.1 shows average growth rate of unit labour cost (ULC) in the manufacturing sector for the period 1982 to 1998 both in national currency and US dollars for Mauritius as well as for some of its trading partners and competitors.

During the period 1982 to 1998, unit labour cost (ULC) in two main Mauritian trading partners, namely France and Germany, have increased more slowly in their national currencies than in dollar term due to some appreciation vis à vis the dollar. As for Mauritius, in rupee term, ULC grew annually by 8.4 per cent during the period under review but in dollar term, the growth works out to 3.3 per cent only due to continuous depreciation of the rupee. This situation has helped the country to maintain its competitiveness. It is interesting to note that the situation of Korea, where ULC in national currency grew by 2 per cent annually between 1982 and 1998, but in dollar term, an annual decline of 2.1 per cent is observed due to a substantial devaluation of its currency in 1998.

**Figure 4.1 - International Comparison of Growth Rate in Unit Labour Cost
Manufacturing, 1982 to 1998**

4.3 International comparison of hourly labour cost in the textile industry for 1998

Country	Hourly labour cost (US\$)	Country	Hourly labour cost (US\$)
Indonesia	0.24	Portugal	4.51
Pakistan	0.40	Taiwan	5.85
Madagascar	0.41	New Zealand	6.49
Bangladesh	0.43	Israel	6.98
Kenya	0.46	Greece	7.99
Zambia	0.48	Spain	8.49
Sri Lanka	0.49	Ireland	10.76
India	0.60	Australia	11.39
China	0.62	USA	12.97
Thailand	1.09	UK	13.58
Phillipines	1.12	Canada	13.93
Mauritius	1.41	France	14.16
Tunisia	1.76	Italy	15.81
South Africa	2.05	Sweden	19.41
Chile	3.16	Japan	20.70
Venezuela	3.30	Germany	21.48
South Korea	3.63	Denmark	23.10
Brazil	4.05		

Source: Werner International

Another indicator pertinent to the manufacturing sector is the hourly labour cost, which includes social benefits and fringes. In Mauritius, the textile industry contributes a major share to the output of the manufacturing sector and the table above shows comparative hourly labour cost of the textile industry in Mauritius as well as in some of its competitors.

Chapter V

METHODOLOGY - CONCEPT AND DEFINITIONS

5.1 Productivity indicators

1. Real output

Real output is given by value added at constant prices. Value added is the value of any industry's final output less its purchases of intermediate products , raw materials and services. Value added is also equal to the amount available for distribution to the factors of production in the form of wages and salaries, profits, rent, allowance for depreciation, interest and dividends.

Output index shows the rate of change in production as compared to a chosen base period.

$$\text{Output index} = \frac{\text{Value added (constant price), year } n}{\text{Value added in base year}} \times 100$$

2. Employment/Labour input

Labour refers to the total number of persons engaged, that is employers, own account workers, contributing family workers and employees in any type of economic activity. Labour and employment are used interchangeably throughout this report. Employment figure for a specific year n is the average number of persons engaged in June of year (n) and June of year (n+1).

A more accurate measure of labour input would be total number of hours worked. However, in the absence of data on manhours, total number of persons engaged in a particular year is used.

The labour input index shows the rate of change in employment.

$$\text{labour input index} = \frac{\text{Number of persons engaged at year } n}{\text{Number of persons engaged in base year}} \times 100$$

3. Capital input

In the absence of data on services provided by capital, an estimate of stock of fixed capital is used. Capital refers to the net stock of investment in reproducible fixed assets. Reproducible fixed assets are investments in residential and non-residential building (excluding land), infrastructural work, machinery and equipment.

The standard **Perpetual Inventory Method (PIM)** has been used for the estimation of the net Capital Stock .For further details on the PIM approach please refer to the section on estimates of capital stock.

Capital input index shows the rate of change in capital. This estimate uses net capital stock at constant prices.

$$\text{Capital input index} = \frac{\text{Stock of fixed capital year } n}{\text{Stock of fixed capital in base year}} \times 100$$

4. Multifactor input

The multifactor input is a weighted combination of inputs, namely labour and capital. The share of "Gross Operating Surplus" in value added is used to weigh capital and labour.

5. Labour productivity

Labour productivity is conventionally measured as the ratio of real output to labour input. Although this measure relates output to the number of employees, it does not measure the specific contribution of labour as a single factor of production. Rather, it reflects the joint effects of many influences, including new technology, capital investment, capacity utilisation, energy use, and managerial skills, as well as the efforts of the workforce.

Labour productivity index shows the rate of change in output per person engaged.

$$\text{Labour Productivity Index} = \frac{\text{Output index}}{\text{Labour input index}} \times 100$$

6. Capital productivity

Capital productivity is the index of the ratio of real output to stock of fixed capital used in the production process. This index should be interpreted with care since partial measures can be very misleading if taken alone, as they include amongst other factors, the effects of the substitution of one resource for another, such as capital for labour.

The capital productivity index shows the rate of change in output per unit of capital.

$$\text{Capital Productivity Index} = \frac{\text{Output index}}{\text{Capital input index}} \times 100$$

7. Multifactor productivity

The limitation of partial productivity measures such as labour and capital productivity indices is that they attribute to one factor of production, changes in efficiency that are attributable to other factors including qualitative factors such as better management, improved quality of

inputs through training and technology as well as higher quality products and economies of scale. A measure of growth in efficiency which takes account of changes in the most important factors; labour and capital is given by the MFP growth. MFP is calculated as the ratio of output to a weighted combination of labour and capital inputs.

Multifactor productivity index

$$\text{MFP index} = \frac{\text{Output index}}{\text{Multifactor input index}} \times 100$$

$$A(t) = \frac{Q(t)}{\{WL(t) \times L(t)\} + \{WK(t) \times K(t)\}} \times 100$$

$WL(t)$ = Labour's input share in time t (ratio of compensation of employees to value added)

$L(t)$ = Labour input index in time t

$WK(t)$ = Capital share in time t (ratio of gross operating surplus to value added)

$K(t)$ = Capital input index in time t

$$WL(t) + WK(t) = 1$$

8. Capital - labour ratio

The Capital - labour ratio gives the proportion of stock of fixed capital to labour inputs. If the ratio increases, capital deepening takes place whilst, when it declines capital widening occurs.

$$\text{Capital - labour ratio} = \frac{\text{Real fixed capital utilised in an industry}}{\text{Number of persons engaged in the industry}}$$

9. Capital - output ratio

The capital - output ratio is the units of capital required to produce one unit of output. This ratio indicates how efficiently investment is contributing to economic growth.

$$\text{Capital - output ratio} = \frac{\text{Real fixed capital stock in a specific year}}{\text{Real GDP at factor cost for the same year}}$$

5.2 Competitiveness indicators

“Competitiveness is the degree to which a nation can, under free and fair market conditions, produce goods and services that meet the test of international markets while simultaneously maintaining or expanding the real incomes of its citizens”. Some of the competitiveness indicators have been computed and presented in this report.

1. Labour cost index

Labour cost , given by compensation of employees, as defined for National Accounts purposes, includes wages and salaries in cash and kind, bonus, overtime and social contribution incurred by employers.

2. Unit labour cost index (ULC)

Unit labour cost is the remuneration of labour to produce one unit of output. It is computed as the ratio of the labour cost index to an index of production. The index shows the rate of change in labour cost per unit of output.

$$\text{Unit labour cost index} = \frac{\text{Labour cost index}}{\text{Output index}} \times 100$$

3. Real exchange rate

The exchange rate quoted at a certain time is the nominal exchange rate. The real exchange rate takes price movements (inflation) into account. This is done by adjusting the nominal exchange rate by the ratio of local prices to that of the other country.

Although many international transactions take place in US dollars, it is often necessary to get an indication of the average movement of a currency against that of its major trading partners. This is desirable as the exchange rate may appreciate against some and depreciate against others.

4. Effective exchange rate

The effective exchange rate shows the trade weighted movement of the home currency against those of its main trading partners. A net effect in nominal terms is obtained as it combines both appreciations and depreciations which might have occurred between the local currency and those of its respective trading partners.

5. Real effective exchange rate

The real effective exchange rate combines the effect of the real and effective exchange rates. It indicates the extent of under or over valuation of the home currency, if purchasing power parity existed in the base year. This is accomplished by adjusting the exchange rate by the ratio of the domestic country's price index in the current period to the foreign country's price index in the

same period . The deflators used could be the CPI, ULC, PPP, GDP deflator, etc. and combining these various country price effects by weighing them with each country's trade weight respectively.

6. Purchasing power parity (PPP)

Purchasing power parity between two countries is the number of units of a country's currency which endows the holder with the same amount of purchasing power (buying power for goods and services) as would one unit of the currency of the other country. The PPP process can be combined with the effective exchange rate and relative price movements to obtain a new PPP or the extent of variation from it by what is also called a real effective exchange rate.

7. Terms of trade index

Trends in the terms of trade index measures the price movements of exports relative to imports. It is the ratio of the export price index to the import price index. A rise in this ratio means that a smaller volume of exports will pay for a larger volume of imports while a decline indicates an unfavourable movement as a larger volume of exports must pay for the same volume of imports. The absolute level of the terms of trade is not significant.

$$\text{Terms of trade} = \frac{\text{Export price index}}{\text{Import price index}} \times 100$$

8. Export ratios

8.1 Openness

The openness of the economy is given by the ratio of total trade " exports + imports" to GDP.

$$\text{Openness} = \frac{\text{Exports} + \text{Imports}}{\text{Domestic production(GDP)}} \times 100$$

8.2 Net export ratio

$$\text{Net export ratio} = \frac{\text{Exports} - \text{Imports}}{\text{Domestic production (GDP)}} \times 100$$

If the net export ratio declines it could mean

- (i) deterioration in the terms of trade
- (ii) structural shift in production from less import intensive to higher import intensive industries i.e. capital intensive technology.
- (iii) export markets are being eroded
- (iv) export incentives have been reduced.

8.3 Net export to export ratios

$$\text{Net export to export ratio} = \frac{\text{Exports} - \text{Imports}}{\text{Exports}} \times 100$$

If the net export to export ratio declines it could mean

- (i) deterioration in the terms of trade
- (ii) structural shift in production from less import intensive to higher import intensive industries i.e. capital intensive technology.
- (iii) higher value added to relatively lower value added activities
- (iv) higher import intensity of exports.

8.4 Export growth, market growth and market penetration

If the share of a country's (Mauritius) export growth of a product or service (say T-shirts) in the market in which it is sold, equals the growth of the imports of the buying country, it can be said that the exporting country (Mauritius) is maintaining its share of the market growth. If the growth is higher, the exporting country (Mauritius) is penetrating the importing countries market. On the other hand, if the growth is lower, the exporting country is losing its market share.

5.3 Estimates of Capital Stock

The Perpetual Inventory Method (PIM)

The Perpetual Inventory Method (PIM) has been used to produce estimates of the value of the stock of capital assets used in the production process. Capital assets refer to tangible reproducible fixed assets which include, building (excluding land), infrastructural work, machinery and equipment. The PIM requires current price estimates of Gross Domestic Fixed Capital Formation and price indexes over many years, and assumptions about the expected lifetime of the respective assets as shown in table 5.1.

The PIM produces annual estimates of gross and net capital stock at constant and current prices by accumulating past flows of expenditure on Gross Domestic Fixed Capital Formation (GDFCF).

Consumption of fixed capital

Consumption of fixed capital is a cost of production. It may be defined in general terms as the decline, during the course of the accounting period, in the current value of the stock of fixed assets owned and used by a producer as a result of physical deterioration, normal obsolescence or normal accidental damage.

Gross capital stock is the accumulation of past investment flows less retirements before deduction of any allowances for consumption of fixed capital.

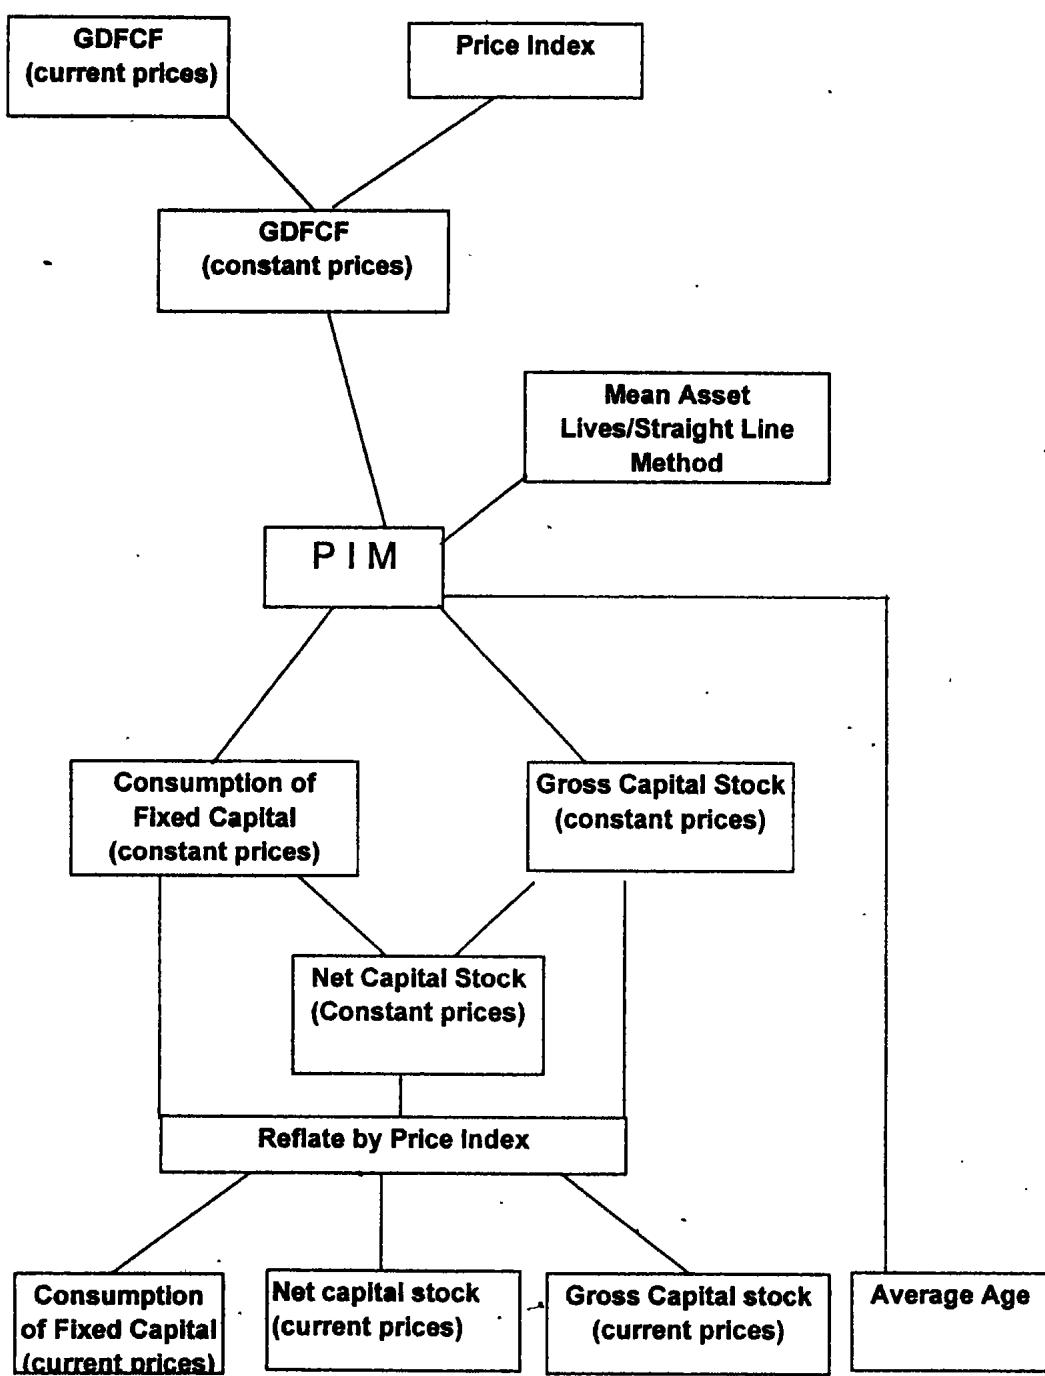

Net capital stock is gross capital stock less accumulated capital consumption on items forming the gross capital stock.

Annual estimates of consumption of fixed capital have been derived using the **Straight Line Method**. The straight line method is recommended in the System of National Accounts (SNA). The straight line depreciation function assumes a linear decline in efficiency, that is, it exhibits the same loss every year until the service life ends when efficiency declines to zero.

Table 5.1: Assumption used for mean asset life by type

Type of asset	Mean asset life
A . Construction Work	Age
Residential building	30 years
Non residential building	40 years
Roads	Indefinite
Other construction work	35 years
B. Transport equipment according to type / sector	
Motor car	8 years
Other transport equipment by sector	
Agriculture	15 years
Manufacturing	8 years
Aircraft /Ship	20 years
Other sectors	12 years
C. Other machinery and equipment by sector	
Agriculture	15 years
Manufacturing	8 years
Financial services	5 years
Public utilities	20 years
Other sectors	12 years

Flow Chart of the PIM process (Perpetual Inventory Method)

A. THE TOTAL ECONOMY

Table A.1 - Trends in Labour Productivity - Total Economy, 1982 to 1998

Year	Real output		Labour input		Labour productivity	
	Index	Growth rate (%)	Index	Growth rate (%)	Index	Growth rate (%)
1982	100.0		100.0		100.0
