LIFE TABLE FOR THE POPULATION OF MAURITIUS  
1961-1963

Computed in the Central Statistical Office by Miss Edith Adams,  
United Nations Demographer.

## Construction of the Life Table

The basic data used in constructing the life table are the following:

(1) Data on the population 5 years of age and over, classified by sex and 5-year age groups, from the population census of June 1962. Data for age groups 75 and over in the case of males, and 60 and over in the case of females, were adjusted for over-statement of age.

(2) The number of registered deaths, classified by sex and 5-year age groups, in the calendar years 1961, 1962 and 1963, i.e. during the 3-year period centered on the census date. Data for age groups 75 and over in the case of males, and 60 and over in the case of females, were adjusted for over-statement of age. Registered deaths for females in the age range from 10 to 30 were smoothed to give a more logical pattern of death rates by age.

From these data, age-specific death rates ( ${}_n m_x$ ) were computed, and  ${}_n q_x$  was derived from the formula:

$${}_n q_x = \frac{2n \cdot n^m_x}{2 + n \cdot n^m_x}$$

where  $n$  is the age class interval.

The procedure was to first compute an abridged life table with  $n = 5$  in the age range from 5 to 84 years. The abridged life table  $5d_x$  values were then interpolated to obtain single age values of  $d_x$  by use of Beers' minimized fifth difference formula. Other life table functions for single years of age were then derived by the usual formulae.

Life table death rates at ages under 5 years were computed from data on registered births and deaths. For computing the infant mortality rate, birth statistics tabulated by calendar quarters for the years 1960-63, and death statistics tabulated by quarter years of age for the years 1961-63 were used. For computing  $q_x$  rates at ages 1, 2, 3 and 4, statistics of births, and of deaths affecting these ages, in the calendar years 1956 to 1963 were used.

${}_n L_x$  values at the early ages of life were derived by the following formulae:

$$L_0 = .25l_0 + .75l_1$$

$$L_1 = .4l_1 + .6l_2$$

For higher ages,  $L_x$  values were derived by the usual formula:

$$L_x = .5 (l_x + l_{x+1})$$

The various functions of the life table are defined as follows:

$d_x$  = the number dying between age  $x$  and  $x + 1$

$q_x$  = the probability at age  $x$ , of dying within one year, i.e. before reaching age  $x+1$

$p_x$  = the probability at age  $x$ , of surviving to age  $x + 1$

$l_x$  = number surviving to exact age  $x$  out of 100,000 born alive

$L_x$  = number of years lived by the cohort between age  $x$  and  $x + 1$

$T_x$  = number of years lived by the cohort after age  $x$

$e'_x$  = average number of years lived after age  $x$ .
